In the Last Class…

- **The searching problem**
  - o "Architecture" of data

- *logn* **search**
  - o Binary search
    - In a more general sense
  - o Red-black tree: balanced BST
    - Definition
      - o Black height constraint for balance
      - o Color constraint for low maintenance cost
    - Operation
      - o Insertion, deletion

Hashing

- **The searching problem**
  - o The ambition of hashing

- **Hashing**
  - o Brute force table: direct addressing
  - o Basic idea of hashing

- **Collision Handling for Hashing**
  - o Closed address hashing
 - o Open address hashing

- **Amortized Analysis**
  - o Array doubling

Cost for Searching

- **Brute force**
  - O(n)

- **Balanced BST**
  - O(logn)

- **Hashing – almost constant time**
  - O(1+α)

- **"Mission impossible"**
  - O(1)

Searching - a Brute Force Approach

- **Direct-address table**
  - Take into account the *whole universe* of keys

Direct-address Table

DIRECT-ADDRESS-SEARCH (T, k)
   return T[k]
DIRECT-ADDRESS-INSERT (T, x)
   T[key[x]] := x
DIRECT-ADDRESS-DELETE (T, x)
   T[key[x]] := NIL

Hashing: the Idea

Hash Table (in feasible size)

E[0]

E[1]

E[*k*]

E[*m*-1]

• *Index distribution*
• *Collision handling*

Hash Function

$H(x)=k$

A calculated array index for the key

quite large, but only a small part is used in an application

x

Key Space

Value of a specific key

Collision Handling: Closed Address

Each address is a linked list

k_1 — k_4

k_5 — k_2 — k_7

Insert to the **head** of the list

k_6 — k_3
Closed Address - Analysis

- **Assumption - simple uniform hashing**

  o For $j=0,1,2,...,m-1$, the average length of the list at $E[j]$ is n/m.

- **The average cost for an unsuccessful search**

  o Any key that is not in the table is equally likely to hash to any of the m address.

  o Total cost $\Theta(1+n/m)$

    - The average cost to determine that the key is not in the list $E[h(k)]$ is the cost to search to the end of the list, which is n/m.

Closed Address - Analysis

- **For successful search** (assuming that x_i is the ith element inserted into the table, i=1,2,...,n)
  - For each i, the probability of that x_i is searched is $1/n$.
  - For a specific x_i, the number of elements examined in a successful search is $t+1$, where t is the number of elements inserted into the same list as x_i, after x_i has been inserted

$$1 + \frac{1}{n} \sum_{i=1}^{n} (1 + t)$$

- **How to compute t?**
  - Consider the *construction* process of the hash table

Closed Address - Analysis

- **For successful search:** (assuming that x_i is the ith element inserted into the table, $i=1,2,...,n$)
  - For each i, the probability of that x_i is searched is $1/n$.
  - For a specific x_i, the number of elements examined in a successful search is $t+1$, where t is the number of elements inserted into the same list as x_i, after x_i has been inserted. And for any j, the probability of that x_j is inserted into the same list of x_i is $1/m$. So, the cost is:

$$\frac{1}{n} \sum_{i=1}^{n} \left(1 + \sum_{j=i+1}^{n} \frac{1}{m} \right)$$

Expected number of elements in front of the searched one in the same linked list.

Closed Address: Analysis

- **The average cost of a successful search:**
  o Define α=n/m as *load factor*,

  The average cost of a successful search is :

  $$\frac{1}{n}\sum_{i=1}^{n}\left(1+\sum_{j=i+1}^{n}\frac{1}{m}\right)=1+\frac{1}{nm}\sum_{i=1}^{n}(n-i)=1+\frac{1}{nm}\sum_{i=1}^{n-1}i$$

  $$=1+\frac{n-1}{2m}=1+\frac{\alpha}{2}-\frac{\alpha}{2n}=\Theta(1+\alpha)$$

  Number of elements in front of the
  searched one in the same linked list

Collision Handling: Open Address

- **All elements are stored in the hash table**
  - No linked list is used
  - The load factor α cannot be larger than 1

- **Collision is settled by "rehashing"**
  - A function is used to get a new hashing address for each collided address
    - The hash table slots are *probed* successively, until a valid location is found.

- **The probe sequence can be seen as a permutation of (0,1,2,..., *m*-1)**

Linear Probing: An Example

Index | H

Index	H
0	**1776**
1	
2	
3	**1055**
4	**1492**
5	1812
6	**1918**
7	1945

rehashing

Hash function: **h(x)=5x mod 8**

1812

hashing

hashing

1945

Rehash function: **rh(j)=(j+1) mod 8**

chain of rehashings

Commonly Used Probing

Linear probing:

Given an ordinary hash function h', which is called an auxiliary hash function, the hash function is: **(clustering may occur)**

$$h(k,i) = (h'(k)+i) \bmod m \quad (i=0,1,...,m\text{-}1)$$

Quadratic Probing:

Given auxiliary function h' and nonzero auxiliary constant c_1 and c_2, the hash function is: **(secondary clustering may occur)**

$$h(k,i) = (h'(k)+c_1 i+ c_2 i^2) \bmod m \quad (i=0,1,...,m\text{-}1)$$

Double hashing:

Given auxiliary functions h_1 and h_2, the hash function is:

$$h(k,i) = (h_1(k)+ ih_2(k)) \bmod m \quad (i=0,1,...,m\text{-}1)$$

Equally Likely Permutations

- **Assumption**
  - Each key is equally likely to have any of the $m!$ permutations of $(1,2...,m)$ as its probe sequence

- **Note**
  - Both linear and quadratic probing have only m distinct probe sequence, as determined by the first probe

Analysis for Open Address Hashing

- **The average number of probes in an unsuccessful search is at most 1/(1-α) (α=*n*/*m*<1)**

  o Assuming uniform hashing

  The probability of the first probed position being occupied is $\frac{n}{m}$, and that of the $j^{th}(j > 1)$ position occupied is $\frac{n-j+1}{m-j+1}$. So the probability of the number of probes no less than i will be:

  $$\frac{n}{m} \cdot \frac{n-1}{m-1} \cdot \frac{n-2}{m-2} \cdot \cdots \cdot \frac{n-i+2}{m-i+2} \le (\frac{n}{m})^{i-1} = \alpha^{i-1}$$

  The the average number of probe is: $\sum_{i=1}^{\infty} \alpha^{i-1} = \sum_{i=0}^{\infty} \alpha^{i} = \frac{1}{1-\alpha}$

  See [CLRS] p.1199, C.25

Analysis for Open Address Hashing

- **The average cost of probes in an successful search is at most** $\dfrac{1}{\alpha}\ln\dfrac{1}{1-\alpha}$ **(α=*n*/*m*<1)**

  o Assuming uniform hashing

To search for the $(i+1)^{th}$ inserted element in the table, the cost is the same as that for inserting it when there are just i elements in the table. At that time, $\alpha = \frac{i}{m}$. So the cost is $\frac{1}{1-\frac{i}{m}} = \frac{m}{m-i}$.

So the average cost for a successful search is:

For your reference:
Half full: 1.387;
90% full: 2.559

$$\frac{1}{n}\sum_{i=0}^{n-1}\frac{m}{m-i} \;=\; \frac{m}{n}\sum_{i=0}^{n-1}\frac{1}{m-i} = \frac{1}{\alpha}\sum_{i=m-n+1}^{m}\frac{1}{i}$$

$$\leq \;\; \frac{1}{\alpha}\int_{m-n}^{m}\frac{dx}{x} = \frac{1}{\alpha}\ln\frac{m}{m-n} = \frac{1}{\alpha}\ln\frac{1}{1-\alpha}$$

Hash Function

- **A good hash function satisfies the assumption of simple uniform hashing**
  - Heuristic hashing functions
    - The division method: $h(k)=k \bmod m$
    - The multiplication method: $h(k)=\lfloor m(kA \bmod 1)\rfloor$ (0<A<1)
  - No single function can avoid the worst case $\Theta(n)$.
    - So "universal hashing" is proposed.
  - Rich resource about hashing function
    - Gonnet and Baeza-Yates: Handbook of Algorithms and Data Structures, Addison-Wesley, 1991.

Array Doubling

- **Cost for search in a hash table is $\Theta(1+\alpha)$**
  - If we can keep α constant, the cost will be $\Theta(1)$
- **What if the hash table is more and more loaded?**
  - Space allocation techniques such as array doubling may be needed
- **The problem of "unusually expensive" individual operation**

Looking at the Memory Allocation

- **hashingInsert(HASHTABLE *H*, ITEM *x*)**
- **integer *size*=0, *num*=0;**
- **if *size*=0 then allocate a block of size 1; *size*=1;**
- **if *num*=*size* then**
- **allocate a block of size 2*size*;**
- **move all item into new table;**
- ***size*=2*size*;**
- **insert *x* into the table;**
- ***num*=*num*+1;**
- **return**

Insertion with expansion: cost *size*

Elementary insertion: cost 1

Worst-case Analysis

- **For n execution of insertion operations**
  - A bad analysis: the worst case for one insertion is the case when expansion is required, up to n

  Of course NOT!

  - So, the worst case cost is in $O(n^2)$.

- **Note the expansion is required during the ith operation only if $i=2^k$, and the cost of the ith operation**

$$c_i = \begin{cases} i & \text{if } i-1 \text{ is exactly the power of 2} \\ 1 & otherwise \end{cases}$$

So the total cost is: $\sum_{i=1}^{n} c_i \leq n + \sum_{j=0}^{\lfloor \log n \rfloor} 2^j < n + 2n = 3n$

Amortized Analysis – Why?

- **Unusually expensive operations**
  - E.g., Insert-with-array-doubling
- **Relation between expensive and usual operations**
  - Each piece of the doubling cost corresponds to some previous insert

Amortized Analysis – How?

- **Amortized equation:**

  amortized cost = actual cost + accounting cost

- **Design goals for accounting cost**
  - In any legal sequence of operations, the sum of the accounting costs is nonnegative
  - The amortized cost of each operation is fairly regular, in spite of the wide fluctuate possible for the actual cost of individual operations

Multi-pop Stack

Pop:
Cost=1

MultiPop:
Cost=min(s,t)

Push:
Cost=1

s t
Amortized cost: push:2; pop, multipop: 0

Multi-pop Stack

- **Why non-negative accounting cost?**
  - For any possible sequence of operations?

	Amortized	Actual	Accounting
Push	2	1	1
Multi-pop	0	k	-k

k is the number of elements upon multi-pop

Binary Counter

0	0 0 0 0 0 0 0 0	0
1	0 0 0 0 0 0 0 1	1
2	0 0 0 0 0 0 1 0	3
3	0 0 0 0 0 0 1 1	4
4	0 0 0 0 0 1 0 0	7
5	0 0 0 0 0 1 0 1	8
6	0 0 0 0 0 1 1 0	10
7	0 0 0 0 0 1 1 1	11
8	0 0 0 0 1 0 0 0	15
9	0 0 0 0 1 0 0 1	16
10	0 0 0 0 1 0 1 0	18
11	0 0 0 0 1 0 1 1	19
12	0 0 0 0 1 1 0 0	22
13	0 0 0 0 1 1 0 1	23
14	0 0 0 0 1 1 1 0	25
15	0 0 0 0 1 1 1 1	26
16	0 0 0 1 0 0 0 0	31

Cost measure: bit flip

amortized cost:

set 1: 2

set 0: 0

Binary Counter

- **Why non-negative accounting cost?**
  o For any possible sequence of operations?

	Amortized	Actual	Accounting
Set 1	2	1	1
Set 0	0	1	-1

Array Doubling

- **Why non-negative accounting cost?**
  - For any possible sequence of operations?

	Amortized	Actual	Accounting
Insert (normal)	3	1	2
Insert (doubling)	3	k+1	-k+2

k is the number of elements upon doubling

Thank you!

Q & A
